Mathematical Statistics

Miscellaneous

Definition
$\Gamma(\alpha)$ denotes the gamma function which is defined as $\Gamma(\alpha) = \int_0^\infty t^{\alpha-1}e^{-t}\,\mathrm{d}t$, where $\alpha > 0$. It is a commonly used extension of the factorial function.

Theorem
The Gamma function has the following properties:

1. The improper integral converges for all $\alpha > 0$.
2. $\Gamma(\alpha) > 0$ for all $\alpha > 0$, $\Gamma(\alpha) \to \infty$ as $\alpha \to 0$.
3. $\Gamma(1) = 1$
4. $\Gamma(\alpha + 1) = \alpha\Gamma(\alpha)$
5. For $n \in \mathbb{N}$, $\Gamma(n) = (n-1)!$
6. $\Gamma(\frac{1}{2}) = \sqrt{\pi}$

Definition
For $\alpha > 0, \beta > 0$, the beta function is defined as $B(\alpha, \beta) = \int_0^1 x^{\alpha-1}(1-x)^{\beta-1}dx$.

Alternatively, the beta function can be written as $B(\alpha, \beta) = \int_0^\infty \frac{t^{\alpha-1}}{(1+t)^{\alpha+\beta}}dt$

Proposition (Relation between beta function and gamma function)

$$B(\alpha, \beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$$

Proposition (Limit Comparison Test for Improper Integrals)
Let $a \in \mathbb{R}$ and $f, g : [a, \infty) \to \mathbb{R}$ be such that both f and g are integrable on $[a, x]$ for every $x \geq a$ with $f(t) > 0$ and $g(t) > 0$ for all large t.
Assume that $\lim\limits_{t\to\infty} \dfrac{f(t)}{g(t)} = l$ where $l \in [0, \infty]$. Then:

- If $l \in (0, \infty)$, then $\displaystyle\int_a^\infty f(x)dx$ converges $\iff$ $\displaystyle\int_a^\infty g(x)dx$ converges
- If $l = 0$, and $\displaystyle\int_a^\infty g(x)dx$ converges then $\displaystyle\int_a^\infty f(x)dx$ converges
- If $l = \infty$ and $\displaystyle\int_a^\infty f(x)dx$ converges then $\displaystyle\int_a^\infty g(x)dx$ converges absolutely

Proposition
Let (a_n) be a sequence of real numbers such that $a_n \to a$. Then $\lim\limits_{n\to\infty} \left(1 + \dfrac{a_n}{n}\right)^n = e^a$

Definition
The **indicator function** of the set A is defined as $I_A(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{otherwise} \end{cases}$

Definition
If $f(t)$ is a function defined for all $t \geq 0$, its Laplace transform is defined as $F(s) = \displaystyle\int_0^\infty e^{-st} f(t)dt$ where s is a real number

Note
Laplace transform $F(s)$ may not exist for all real number s.

Theorem
If $f(t)$ is defined and piecewise continuous on every finite subinterval of $(0, \infty)$ and satisfies the following growth restriction $|f(t)| \leq Me^{ct}$ for all $t \geq 0$ and some constants $M > 0$ and $c \in \mathbb{R}$, the Laplace transform $F(s)$ exists for all $s \geq c$.

Theorem
If the Laplace transform of a given function exists, it is uniquely determined.
Conversely, if two functions have the same transform, these functions cannot differ over an interval of positive length.
If two continuous functions have the same transform, they are completely identical.

Fundamentals

Definition
Two random vectors $(X_1, X_2, ..., X_n)$ and $(Y_1, Y_2, ..., Y_n)$ are said to be **independent** if $F(x_1, x_2, ..., x_m, y_1, y_2, ..., y_n) = F_1(x_1, x_2, ..., x_m)F_2(x_1, x_2, ..., x_n)$ for all $(x_1, x_2, ..., x_m, y_1, y_2, ..., y_n) \in \mathbb{R}^{m+n}$ where F, F_1, F_2 are the joint CDF's of $(X_1, X_2, ..., X_m, Y_1, Y_2, ..., Y_n)$, $(X_1, X_2, ..., X_m)$ and $(Y_1, Y_2, ..., Y_n)$ respectively.

Theorem
Let $X = (X_1, X_2, ..., X_m)$ and $Y = (Y_1, Y_2, ..., Y_n)$ be independent random vectors. Then the component X_j of $X(j = 1, 2, ..., m)$ and the component Y_k of $Y(k = 1, 2, ..., n)$ are independent random variables. If h and g are Borel-measurable functions, $h(X_1, X_2, ..., X_m)$ and $g(Y_1, Y_2, ..., Y_n)$ are independent.

Theorem
Suppose (X, Y) have joint pdf f. Then X and Y are independent iff for some constant $k > 0$ and non-negative functions f_1 and f_2, $f(x, y) = kf_1(x)f_2(y)$ for all $(x, y) \in \mathbb{R}^2$

Theorem
Let X be a random variable with pdf $f(x)$. Then the pdf of $aX + b$ where $a \neq 0, b \in \mathbb{R}$ is given by $\frac{1}{a} f\left(\frac{x-b}{a}\right)$

Theorem
If X and Y are independent continuous random variables with pdfs $f_X(x)$ and $f_Y(y)$, then the pdf of $Z = X + Y$ is $f_Z(z) = \int_{-\infty}^{\infty} f_X(w) f_Y(z-w) \, \mathrm{d}w$

Proposition
Let (X, Y) be a random vector with joint density $f(x, y)$ and g, h be continuous and differentiable real valued functions of two variables. Then to obtain the joint pdf of $(g(X, Y), h(X, Y))$ we consider the equations $g(x, y) = z$ and $h(x, y) = w$. There may be many such points (x, y) which map to z and w under g and h respectively. Let the points $(x_1, y_1), (x_2, y_2), ..., (x_n, y_n)$ represent the points which satisfy $g(x_i, y_i) = z$ and $h(x_i, y_i) = w$.
We can find these points as $\{x_i\} = g^{-1}(z, w)$ and $\{y_i\} = h^{-1}(z, w)$.

Compute $J(x_i, y_i) = \begin{bmatrix} \frac{\partial g}{\partial x} & \frac{\partial g}{\partial y} \\ \frac{\partial h}{\partial x} & \frac{\partial h}{\partial y} \end{bmatrix}_{(x=x_i, y=y_i)}$

Then the joint pdf is $k(z, w) = \sum_i \frac{1}{|J(x_i, y_i)|} f(x_i, y_i)$

Expectation, Variance and Moments

Definition
The **expectation** of a discrete random variable X having values $x_1, x_2, ..., x_n$ and probability function $f(x)$ is defined as $E(X) = \sum_{i=1}^{n} x_i f(x_i)$.

If X is a discrete random variable taking on infinite set of values $x_1, x_2, ...,$ then $E(X) = \sum_{i=1}^{\infty} x_i f(x_i)$ provided the infinite series converges absolutely.

For a continuous random variable X with distribution function $f(x)$, the expectation of X is defined as $E(X) = \int_{-\infty}^{\infty} x f(x) dx$ provided the integral converges absolutely.

Theorem
The expectation has the following properties:

1. $E(cX) = cE(X)$ where c is any constant
2. If X and Y are any random variables then $E(X + Y) = E(X) + E(Y)$
3. If X and Y are independent random variables, then $E(XY) = E(X)E(Y)$

Definition
The **variance** is defined as $\text{Var}(X) = \sigma^2 = E[\,(X-\mu)^2\,]$. The **standard deviation** is defined as $\sigma = \sqrt{\text{Var}(X)}$.

Theorem
The variance has the following properties:

1. $\sigma^2 = E\left[(X-\mu)^2\right] = E\left(X^2\right) - \mu^2 = E\left(X^2\right) - [E(X)]^2$ where $\mu = E(X)$
2. If c is any constant, $\text{Var}(cX) = c^2\text{Var}(X)$
3. The quantity $E[(X-a)^2]$ is a minimum where $a = \mu = E(X)$
4. If X and Y are independent random variables, then
   $\text{Var}(X+Y) = \text{Var}(X) + \text{Var}(Y)$ and $\text{Var}(X-Y) = \text{Var}(X) + \text{Var}(Y)$

Definition
The r-th **moment** of a random variable X about the mean μ is defined as $\mu_r = E[\ (X-\mu)^r\ ]$ where $r = 0, 1, 2, ...$
The r-th moment of X about the origin is defined as $\mu_r' = E(X^r)$.

It follows that $\mu_0 = 0$, $\mu_1 = 1$, $\mu_2 = \sigma^2$

Theorem (Law of the unconscious statistician - LOTUS)
Let X be a discrete random variable with probability function $f(x)$. Then $Y = g(x)$ is also a discrete random variable.
The probability function of Y is $h(y) = P(Y = y) = \displaystyle\sum_{\{x|g(x)=y\}} P(X = x) = \displaystyle\sum_{\{x|g(x)=y\}} f(x)$.
If X takes on values $x_1, x_2, ..., x_n$ and Y takes on values $y_1, y_2, ..., y_m$, then $m \leq n$ and $y_1 h(y_1) + y_2 h(y_2) + ... + y_m h(y_m) = g(x_1)f(x_1) + g(x_2)f(x_2) + ... + g(x_n)f(x_n)$ which lets us write the expectation of Y as

$$E(Y) = g(x_1)f(x_1) + g(x_2)f(x_2) + ... + g(x_n)f(x_n) = \sum_{i=1}^{n} g(x_i)f(x_i).$$

Similarly when X is a continuous random variable and $Y = g(X)$, then $E(Y) = \displaystyle\int_{-\infty}^{\infty} g(x)f(x)dx$.

Definition
Let X be a random variable defined on $(\Omega, \mathcal{F}, P)$. The function $M(t) = E\left[e^{tX}\right]$ is called the **moment generating function** (MGF) of the random variable X if the expectation on the right side exists in some neighbourhood of the origin. If the expectation on the right side does not exist in any neighbourhood of the origin, then we say the MGF does not exist.

The r-th derivative of the moment generating funtion is the r-th moment about the origin μ_r'.

Theorem
If the MGF $M(s)$ of a random variable X exists, then the MGF $M(s)$ has derivatives of all orders at $s = 0$ and

$M^{(k)}(s)|_{s=0} = EX^k$ for positive integer k

Theorem
The moment generating function has the following properties:

1. For any constants a and b, the mgf of the random variable $aX + b$ is given by $M_{aX+b} = e^{bt} M_X(at)$

2. If X and Y are independent random variables having moment generating functions $M_X(t)$ and $M_Y(t)$ respectively, then $M_{X+Y}(t) = M_X(t)M_Y(t)$

3. **Uniqueness Theorem** Suppose that X and Y are random variables having moment generating functions $M_X(t)$ and $M_Y(t)$ respectively. Then X and Y have the same probability distribution if and only if $M_X(t) = M_Y(t)$ identically.

Definition
Let $X_1, X_2, ..., X_n$ be a jointly distributed or $(X_1, X_2, ..., X_n)$ be a random vector. If $E[\exp(\sum_{j=1}^{n} t_j X_j)]$ exists for $|t_j| \leq h_j$, $j = 1, 2, ..., n$, we write $M(t_1, t_2, ..., t_n) = E[\exp(t_1 X_1 + t_2 X_2 + ... + t_n X_n)]$ and call it the MGF of $X_1, X_2, ..., X_n$ or simply, the **joint moment generating function** (joint MGF) of the random vector $(X_1, X_2, ..., X_n)$

Theorem
The joint MGF $M(t_1, t_2)$ uniquely determines the joint distribution of (X, Y). Conversely, if the joint MGF exists it is unique.

Theorem
The joint MGF $M(t_1, t_2)$ completely determines the marginal distributions of X and Y.
$M(t_1, 0) = E[\exp(t_1 X)] = M_X(t_1)$ and $M(0, t_2) = E[\exp(t_2 X)] = M_Y(t_2)$

Theorem
X and Y are independent random variables if and only if $M(t_1, t_2) = M(t_1, 0)M(0, t_2)$ for all $t_1 \in [-h_1, h_1], t_2 \in [-h_2, h_2]$

Distributions

Definition
Let p be the probability that an event will happen in any single Bernoulli trial (trial with outcomes either success or failure). The probability that an event will happen exactly x times in n trials is given by the **Binomial Random Variable** with pmf distribution $f(x) = \binom{n}{k} p^x (1-p)^{n-x} = \frac{n!}{x!(n-x)!} p^x (1-p)^{n-x}$, where $x = 0, 1, ..., n$.

Proposition
The binomial random variable has mean $\mu = np$ and variance $\sigma^2 = npq$.

Definition
The **Poisson Random Variable** has pmf distribution $f(x) = \frac{\lambda^x e^{-\lambda}}{x!}$, $x = 0, 1, 2, ...$ and $\lambda > 0$.

Proposition
The Poisson Random Variable has mean $\mu = \lambda$ and variance $\sigma^2 = \lambda$.

Proposition
The Poisson Random Variable with $\lambda = np$ is the limiting case of the Binomial Distribution. It approximates the Binomial Random variable Binomial(n, p) when n is large and probability of occurrence of an event p is close to 0.

Definition
The **uniform random variable** has the pdf distribution $f(x) = \begin{cases} \frac{1}{b-a} & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases}$.

Proposition
The uniform random variable has mean $\mu = \frac{a+b}{2}$ and variance $\sigma^2 = \frac{1}{12}(b-a)^2$.

Definition
The **exponential random variable** has the pdf distribution $f(x) = \begin{cases} \lambda e^{-\lambda x} & x > 0 \\ 0 & \text{otherwise} \end{cases}$

Proposition
The exponential random variable has mean $\frac{1}{\lambda}$ and variance $\frac{1}{\lambda^2}$.

Definition
The **normal random variable**, also known as the gaussian random variable, has pdf distribution $f(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$ where $-\infty < x < \infty$ where μ and σ are the mean and standard deviation respectively.

Definition
When $\mu = 0$ and $\sigma = 1$, we get the **standard normal random variable** with distribution $f(x) = \frac{1}{\sqrt{2\pi}} \exp(-\frac{x^2}{2})$.

We can write any normal random variable $Y \sim N(\mu, \sigma)$ in terms of the standard normal random variable $X \sim N(0, 1)$ as $Y = \sigma X + \mu$.

Proposition
When n is large and neither p or q is too close to 0, the binomial random variable X can be approximated by a normal distribution with mean np and standard deviation $\sqrt{npq}$. The approximation is very good when $np, nq > 5$.

Proposition
The Poisson Distribution approaches the normal distribution $N(\lambda, \sqrt{\lambda})$ as $\lambda \to \infty$, i.e. the Poisson distribution is asymptotically normal.

Definition
A variable the pdf $f(x) = \frac{1}{\sigma\pi(1 + \left(\frac{x-\mu}{\sigma}\right)^2)}$, $x \in \mathbb{R}$ where $\sigma > 0, \mu \in \mathbb{R}$ is called a **Cauchy random variable** with parameter μ and σ^2. We write $X \sim \mathcal{C}(\mu, \sigma^2)$ for Cauchy random X with pdf.

Definition
When $\mu = 0$ and $\sigma^2 = 1$, we get the **standard Cauchy random variable** $C(0, 1)$ with distribution $f(x) = \frac{1}{\pi(1 + x^2)}$.

We can write any Cauchy random variable $Y = C(\mu, \sigma^2)$ in terms of the standard Cauchy random variable $X = C(0, 1)$ as $Y = \sigma X + \mu$.

Proposition
The mean, variance, higher moments, moment generating function of a Cauchy random variable do not exist.

Definition
A random variable with the pdf $f(x) = \frac{1}{\Gamma(\alpha)\beta^\alpha} x^{\alpha-1} e^{-x/\beta}$ where $0 < x < \infty, \alpha > 0, \beta > 0$ is called a **gamma random variable** $G(\alpha, \beta)$ with parameters α and β.

Proposition
When $\alpha = 1$, we see that the gamma distribution is a generalization of the exponential distribution as
$G(1, \beta) = \exp(\beta)$ with pdf $f(x) = \dfrac{1}{\beta} e^{-x/\beta}$, $x > 0$.

Proposition
The gamma distribution has mean $\mu = \alpha\beta$ and variance $\sigma^2 = \alpha\beta^2$.

Definition
The **chi-square distribution** is
$f(x) = \dfrac{1}{\Gamma(\frac{p}{2}) 2^{\frac{p}{2}}} x^{\frac{p}{2}-1} e^{-x/2}$ where $0 < x < \infty$.

χ^2_p denotes a chi-square random variable with p degrees of freedom.

The chi-square distribution is a special case of the gamma distribution with $\alpha = \dfrac{p}{2}$ and $\beta = 2$.

Proposition
The mean of the chi-square distribution is given by $\mu = p$ and the variance is given by $\sigma^2 = 2p$.

Proposition
Let $X \sim N(0, 1)$. Then $X^2 \sim \chi^2_1$

Proposition
Let $X_1, X_2, ..., X_n$ be independent normal random variables with mean 0 and variance 1. Then $\chi^2 = X_1^2 + X_2^2 + ... + X_p^2$ is chi-square distributed with p degrees of freedom.

Definition
A random variable T has the **Students t-distribution** with p degrees of freedom, and we write $T \sim t_p$ if it has pdf $f_p(t) = \dfrac{\Gamma(\frac{p+1}{2})}{\Gamma(\frac{p}{2})} \dfrac{1}{(p\pi)^{\frac{1}{2}}} \dfrac{1}{(1 + \frac{t^2}{p})^{\frac{(p+1)}{2}}}$ for $-\infty < t < \infty$

Proposition
If $p = 1$, T is a Cauchy$(0, 1)$ distribution with distribution $f_p(t) = \dfrac{\Gamma(1)}{\Gamma(\frac{1}{2})} \dfrac{1}{\pi^{\frac{1}{2}}} \dfrac{1}{1 + t^2}$.
So we will assume that $p > 1$.

Proposition
Let $T \sim t_p$. Then $E[T^r]$ exists for $r < p$ and

$$E[T^r] = \begin{cases} 0 & \text{if } r \text{ is odd} \\ p^{\frac{r}{2}} \dfrac{\Gamma(\frac{r+1}{2})\Gamma(\frac{p-r}{2})}{\Gamma(\frac{p}{2})\Gamma(\frac{1}{2})} & \text{if } r \text{ is even} \end{cases}$$

Proposition
The Students t-distribution has no MGF because it does not have moments of all orders.

Proposition
Let $T \sim t_p$, $p > 2$ be a random variable with Student's t-distribution. Then T has mean $\mu = 0$ and variance $\sigma^2 = \dfrac{p}{p-2}$.

Definition
A random variable $X \sim F(m,n)$ has the ***F*-distribution** with m and n degrees of freedom if it has pdf

$$f_F(t) = \frac{\Gamma\left(\frac{m+n}{2}\right)}{\Gamma\left(\frac{m}{2}\right)\Gamma\left(\frac{n}{2}\right)} \left(\frac{m}{n}\right)^{\frac{m}{2}} \frac{t^{\frac{m}{2}-1}}{(1+\frac{m}{n}t)^{\frac{m+n}{2}}} \text{ where } t > 0$$

Proposition
If $X \sim t_n$, then $X^2 \sim F(1,n)$. In particular if $X \sim C(0,1)$, i.e. $X \sim t_1$, then $X^2 \sim F(1,1)$.

Proposition
Let $X \sim F(m,n)$. Then for $k \in \mathbb{N}$, $E[X^k] = \left(\dfrac{n}{m}\right)^k \dfrac{\Gamma(k+\frac{m}{2})\Gamma(\frac{n}{2}-k)}{\Gamma(\frac{m}{2})\Gamma(\frac{n}{2})}$ for $n > 2k$.

Proposition
Let $X \sim F(m,n)$. Then X has mean $\mu = \dfrac{n}{n-2}$ and variance $\sigma^2 = \dfrac{n^2(2m+2n-4)}{m(n-2)^2(n-4)}$ for $n > 4$.

Definition
A random variable $X \sim \text{beta}(\alpha,\beta)$ has the **beta distribution** if it has pdf $f(x) = \dfrac{1}{B(\alpha,\beta)} x^{\alpha-1}(1-x)^{\beta-1}$ for $0 < x < 1$.

Definition
A random variable X has the **Pareto distribution** with parameters $\alpha > 0$ and $\beta > 0$ if it has pdf

$$f(x) = \begin{cases} \dfrac{\beta\alpha^\beta}{x^{\beta+1}} & x \geq \alpha \\ 0 & x \leq \alpha \end{cases}$$

Proposition
For Pareto's distribution with parameter α and β, the moment of order n exists if and only if $n < \beta$.

Definition
The **Weibull Distribution** (Weibull(γ, β)) has pdf with parameters $\gamma > 0$, $\beta > 0$ defined as $f(x) = \frac{\gamma}{\beta} x^{\gamma-1} \exp(-\frac{x^\gamma}{\beta})$ where $x \geq 0$.

Sampling Theory

We can either sample *with replacement* or *without replacement*. A finite population sampled with replacement can be considered infinite. Sampling from a very large finite population can similarly be considered as sampling from an infinite population.
To properly choose the sample, we can make sure that every member of the population has an equal chance of being in the sample. Normally, since the sample size is much smaller than the population size, sampling without replacement will give practically the same results as sampling with replacement.
For a sample of size n from a population which we assume has distribution $f(x)$, we can choose members of the population at random, each selection corresponding to a random variable $X_1, X_2, ..., X_n$ with corresponding values $x_1, x_2, ..., x_n$. In case we are assuming sampling without replacement, $X_1, X_2, ..., X_n$ will be independent and identically distributed random variables with probability distribution $f(x)$.

Definition
Let X be a random variable with a distribution f, and let $X_1, X_2, ..., X_n$ be iid random variables with the common distribution f.
Then the collection $X_1, X_2, ..., X_n$ is called a **random sample** of size n from the population f.

Since $X_1, X_2, ..., X_n$ are iid, the joint distribution of the random sample is
$f(x_1, x_2, ..., x_n) = f(x_1)f(x_2)...f(x_n)$.
Any quantity obtained from a sample for the purpose of estimating a population parameter is called a sample statistic, or briefly statistic. Mathematically, a sample statistic for a sample of size n can be defined as a function of the random variables $X_1, X_2, ..., X_n$ as $T(X_1, X_2, ..., X_n)$. This itself is a random variable whose values can be represented as $T(x_1, x_2, ..., x_n)$.

Definition
Let $X_1, X_2, ..., X_n$ be a random sample of size n from the population whose distribution is $f(x|\theta)$ (the distribution f with unknown parameter θ). Let $T(x_1, x_2, ..., x_n)$ be a real-valued or vector-valued function whose domain includes the range of $(X_1, X_2, ..., X_n)$. Then the random variable or random vector $Y = T(X_1, ..., X_n)$ is called a **statistic** provided that T is not a function of any unknown parameter θ.

For example consider $X \approx N(\mu, \sigma^2)$ where μ is known but σ is unknown. Then $\frac{\sum_{i=1}^{n} X_i}{\sigma^2}$ is not a statistic but $\frac{\sum_{i=1}^{n} X_i}{\mu^2}$ is a statistic.
Two common statistics are the sample mean and sample variance.

Definition
The **sample mean** is the arithmetic average of the values in the random sample. It is denoted by $\bar{X} = \frac{X_1 + X_2 + ... + X_n}{n}$.

The **sample variance** is the statistic defined by $S^2 = \frac{\sum_{i=1}^{n} \left(X_i - \bar{X}\right)^2}{n-1}$

The **sample standard deviation** is the statistic defined by $S = \sqrt{S^2}$.

Definition
Let $X_1, X_2, ..., X_n$ be a random sample from a population $f(x|\theta)$. We say that a statistic $T(X_1, X_2, ..., X_n)$ is an **unbiased estimator** of the parameter θ if $E(T) = \theta$ for all possible values of θ.

Theorem
Let $X_1, X_2, ..., X_n$ be a random sample from a population with mean μ and variance $\sigma^2 < \infty$. Then:

1. $E\left(\bar{X}\right) = \mu$

2. $\text{Var}\left(\bar{X}\right) = \frac{\sigma^2}{n}$

3. $E\left(S^2\right) = \sigma^2$

From the above theorem we see that the sample mean $\bar{X}$ is an unbiased estimator of the population mean μ and the sample variance S^2 is an unbiased estimator of the population variance σ^2. (The reason we included $\frac{1}{n-1}$ in the definition of the sample variance was to make it an unbiased estimator)

Definition
Let $X_1, X_2, ..., X_n$ be a random sample of size n from a population $f(x|\theta)$. The probability distribution of a statistic $T(X_1, X_2, ..., X_n)$ is called the sampling distribution of T.

Theorem (MGF of the sample mean)
Let $X_1, X_2, ..., X_n$ be a random sample from a population with MGF $M_X(t)$. Then the MGF of the sample mean is $M_{\bar{X}}(t) = (M_X(t/n))^n$.

Theorem
Let $X_1, X_2, ..., X_n$ be a random sample from a $N(\mu, \sigma^2)$ distribution, and let X denote the sample mean.
Then X and the random vector $(X_1 - X, X_2 - X, ..., X_n - X)$ are independent.

Theorem
Let $X_1, X_2, ..., X_n$ be a random sample from a $N(\mu, \sigma^2)$ distribution, and let X denote the sample mean and S^2 denote the sample variance. Then X and S^2 are independent random variables.

The converse of this theorem is also true: if the sample mean and sample variance of a random sample are independent random variables then population distribution is normal.

Theorem
Let $X_1, X_2, ..., X_n$ be a random sample from a $N(\mu, \sigma^2)$ distribution and let $\overline{X}$ denote the sample mean and S^2 denote the sample variance. Then $(n-1)\dfrac{S^2}{\sigma^2}$ has a chi-square distribution with $(n-1)$ degrees of freedom.

Definition
Let $X_1, X_2, ..., X_n$ be a random sample and $x_1, x_2, ..., x_n$ be values taken by these random variables. Arrange $(x_1, x_2, ..., x_n)$ in increasing order of magnitude so, $x_{(1)} \leq x_{(2)} \leq ... \leq x_{(n)}$ where $x_{(1)} = \min(x_1, x_2, ..., x_n)$, $x_{(2)}$ is the second smallest value and so on and $x_{(n)} = \max(x_1, x_2, ..., x_n)$. If any two x_i, x_j are equal, their order does not matter.
The function $X_{(k)}$ of $(X_1, X_2, ..., X_n)$ that takes on the value $x_{(k)}$ in each possible sequence $(x_1, x_2, ..., x_n)$ of values assumed by $(X_1, X_2, ..., X_n)$ is known as the **k-th order statistic**.
$X_{(1)}, X_{(2)}, ..., X_{(n)}$ is called the **set of order statistics** for $(X_1, X_2, ..., X_n)$

Definition
The **sample range** $R = X_{(n)} - X_{(1)}$ is the distance between the smallest and largest observations. It is the measure of the dispersion in the sample and should reflect the dispersion of the population.

Definition
In terms of order statistics, the **sample median** M is defined by

$$M = \begin{cases} X_{(\frac{n+1}{2})} & \text{if } n \text{ is odd} \\ \frac{1}{2}\left[X_{(\frac{n}{2})} + X_{(\frac{n}{2}+1)}\right] & \text{if } n \text{ is even} \end{cases}.$$

Theorem
Let $X_{(1)}, X_{(2)}, ..., X_{(n)}$ denote the order statistics of the random sample $X_1, X_2, ..., X_n$ from a continuous population with cdf $F_X(x)$ and the pdf $f_X(x)$. Then the pdf of $X_{(j)}$ is

$$f_{X_{(j)}}(x) = \frac{n!}{(j-1)!(n-j)!} f_X(x)[F_X(x)]^{j-1}[1-F_X(x)]^{n-j} \text{ for } x \in \mathbb{R}$$

Theorem
Let $X_{(1)}, X_{(2)}, ..., X_{(n)}$ denote the order statistics of the random sample $X_1, X_2, ..., X_n$ from a continuous population with cdf $F_X(x)$ and the pdf $f_X(x)$. Then the joint pdf of all the order statistics is given by

$$f_{X_{(1)},X_{(2)},...,X_{(n)}} = \begin{cases} n! f_X(x_1)...f_X(x_n) & -\infty < x_1 < x_2 < ... < x_n < \infty \\ 0 & \text{otherwise} \end{cases}$$

Theorem
Let $X_{(1)}, X_{(2)}, ..., X_{(n)}$ denote the order statistics of the random sample $X_1, X_2, ..., X_n$ from a continuous population with cdf $F_X(x)$ and the pdf $f_X(x)$. Then the joint pdf of $X_{(i)}$ and $X_{(j)}$ where $1 \le i \le j \le n$ is given by

$$f_{X_{(i)},X_{(j)}}(u,v) = \begin{cases} \dfrac{n! f_X(u) f_X(v)[F_X(u)]^{i-1}[1-F_X(v)]^{n-j}[F_X(v)-F_X(u)]^{j-1-i}}{(i-1)!(j-1-i)!(n-j)!} & -\infty < u < v < \infty \\ 0 & \text{otherwise} \end{cases}$$

Theorem
Suppose $X_1, X_2, ..., X_n$ are iid random variables with common pdf f and CDF F. Let g be a real valued function such that $E|g(X)| < \infty$ where $X \sim F$. Then for $1 \le j \le n$, $E|g(X_{(j)})|$ exists. Converse holds as well.

Note
If $E|g(X_{(j)})| = \infty$ for some j, then $E|g(X)| = \infty$ and conversely,
if $E|g(X)| = \infty$, then $E|g(X_{(j)}| = \infty$ for some j.

Definition
Suppose a sequence of random variables $(X_n)_{n\geq 1}$ and a random variable X are defined on a probability space $(\Omega, \mathcal{F}, P)$. We say that the sequence of random variables $X_1, X_2, ...$ **converges in probability** to the random variable X (written $X_n \xrightarrow{p} X$) if for every $\epsilon > 0$, $\lim_{n\to\infty} P(|X_n - X| > \epsilon) = 0$ or equivalently $\lim_{n\to\infty} P(|X_n - X| \leq \epsilon) = 1$

Note
The random variables in the sequence $X_1, X_2, ...$ are typically not iid random variables

Theorem
Suppose $X_n \xrightarrow{p} X$ and $Y_n \xrightarrow{p} Y$. Then $X_n \pm Y_n \xrightarrow{p} X \pm Y$ and $X_n Y_n \xrightarrow{p} XY$

Theorem
Suppose $X_n \xrightarrow{p} a$, where a is a non-zero constant. Then $\dfrac{1}{X_n} \xrightarrow{p} \dfrac{1}{a}$

Theorem
Let $X_n \xrightarrow{p} X$ and h be a real valued continuous function of a real variable. Then $h(X_n) \xrightarrow{p} h(X)$

Definition
We say that a sequence of estimators $W_n = W_n(X_1, ..., X_n)$ is a **consistent sequence of estimators** of the parameter θ if $W_n \xrightarrow{p} \theta$ as $n \to \infty$ for each fixed $\theta \in \Theta$.

Note
This basically means the estimator converges to the proper value as the sample size becomes infinite, i.e. approaches the size of the population itself.

Theorem (Weak Law of Large Numbers)
Let $X_1, X_2, ..$ be iid random variables with $EX_i = \theta$. Define $\overline{X_n} = \dfrac{1}{n}\sum_{i=1}^{n} X_i$. Then $\overline{X_n} \xrightarrow{p} \theta$.
The weak law of large numbers states that for any population with a finite mean θ, the sample mean $\overline{X_n}$ is a consistent estimator for the population mean θ.

Theorem (Markov's Inequality)
Let X be a random variable with finite r-moment where $r > 0$. Then for every $\epsilon > 0$, $P(|X| \geq \epsilon) \leq \dfrac{E|X^r|}{\epsilon^r}$

Theorem (Chebyshev's Inequality)
Let X be a random variable with finite mean μ and finite variance σ^2. Then for every $\epsilon > 0$, $P(|X - \mu| \geq \epsilon) \leq \dfrac{\sigma^2}{\epsilon^2}$

Theorem
Suppose we have a sequence $X_1, X_2, ...$ of iid random variables with $EX_i = \mu$ and $Var(X_i) = \sigma^2 < \infty$. Define the sample variance $S_n^2 = \dfrac{1}{n-1}\sum_{i=1}^{n}(X_i - \overline{X_n})^2$. Then a sufficient condition that S_n^2 converges in probability to σ^2 is that $Var(S_n^2) \to 0$ as $n \to \infty$.

Theorem
Consider a sequence of estimators W_n each having finite mean and variance. If W_n is a sequence of estimators such that $EW_n \to \theta$ and $Var(W_n) \to 0$ as $n \to \infty$, then W_n is consistent for θ.

Theorem
Let W_n be a consistent sequence of estimators for a parameter θ. Let $a_1, a_2, ...$ and $b_1, b_2, ...$ be sequences of real numbers such that $a_n \to 1$ and $b_n \to 0$. Then the sequence $U_n = a_n W_n + b_n$ is a consistent sequence of estimators of θ.

Theorem
If S_n^2 is a consistent estimator of σ^2, then the sample standard deviation $Sn = \sqrt{S_n^2}$ is a consistent estimator of σ

Definition
Let $X_1, X_2, ..., X_n$ be a random sample. The **sample moment of order** k (where k is a positive integer) is defined as $m_k = \dfrac{1}{n}\sum_{i=1}^{n} X_i^k$

Note
Even if the population does not have any moment, sample moments of all orders exists

Definition
We say that a sequence of random variables $X_1, X_2, ...$ **converges in distribution** to a random variable X (written $X_n \xrightarrow{d} X$) if $\lim_{n\to\infty} F_{X_n}(x) = F_X(x)$ at all points x where $F_X(x)$ is continuous.

Note
The convergence of distribution functions does not imply the convergence of corresponding PMFs or PDFs.

Theorem
Assume that the random variables X and X_n (for each n) are non-negative and integer valued. Then $X_n \xrightarrow{d} X \iff \lim_{n\to\infty} f_{X_n}(k) = f_X(k)$ for all $k = 0, 1, 2, ...$

Theorem
Let (X_n) and X be random variables with pdf such that $f_{X_n}(x) \to f_X(x)$ for almost all $x \in \mathbb{R}$. Then $X_n \xrightarrow{d} X$.

Note
Convergence in distribution does not have the usual properties associated with convergence. For example, unless X_n and Y_n are independent, then in general $X_n \xrightarrow{d} X$ and $Y_n \xrightarrow{d} Y$ does not imply that $X_n + Y_n \xrightarrow{d} X + Y$

Theorem
If $X_n \xrightarrow{d} X$ and $Y_n \xrightarrow{d} a$ where a is a constant, then $X_n + Y_n \xrightarrow{d} X + a$ and $X_n Y_n \xrightarrow{d} aX$

Theorem
If the sequence of random variables $X_1, X_2, ...$ converges in probability to a random variable X, then the sequence also converges in distribution to X.

Note
The converse of the above theorem is not true.

Theorem
Suppose $X_n \xrightarrow{d} a$ where a is a constant. Then $X_n \xrightarrow{p} a$

Theorem (Central Limit Theorem)
Let $X_1, X_2, ...$ be a sequence of independent and identically distributed random variables, each having a finite mean μ and non-zero variance σ^2.
Then $\dfrac{Z_n - n\mu}{\sigma\sqrt{n}} \xrightarrow{d} N(0,1)$ where $Z_n = X_1 + X_2 + ... + X_n$

Theorem (Continuity Theorem)
Let (X_n) be a sequence of random variables with corresponding MGFs (M_n) and suppose that $M_n(t)$ exists for $|t| \le t_0$ for every n. If there exists a random variable X with corresponding MGF M which exists for $|t| \le t_1 \le t_0$ such that $M_n(t) \to M(t)$ as $n \to \infty$ for every $t \in [-t_1, t_1]$ then $X_n \xrightarrow{d} X$.

Definition
Let (X_n) be a sequence of random variables. We say that X_n is **asymptotically normal** with mean μ and variance σ_n^2 and we write X_n is $AN(\mu_n, \sigma_n^2)$ if $\sigma_n > 0$ and $\dfrac{X_n - \mu}{\sigma_n} \xrightarrow{d} N(0,1)$ as $n \to \infty$.

Note
Here μ_n is not necessarily the mean of X_n and σ_n^2 is not necessarily its variance.

Theorem (Delta Method)
Suppose Y_n is $AN(\mu, \sigma^2)$ with $\sigma_n \to 0$ and μ a fixed real number. Let g be a real-valued function which is differentiable at $x = \mu$, with $g'(\mu) \neq 0$. Then $g(Y_n)$ is $AN(g(\mu), [g'(\mu)]^2\sigma_n^2)$

Theorem (k-th order Delta Method)
Suppose Y_n is $AN(\mu, \sigma^2)$ with $\sigma_n \to 0$ and μ a fixed real number. Let g be a real valued function which is differentiable k times, $k \geq 1$ at $x = \mu$ with $g^{(i)}(\mu) = 0$ for $1 \leq i \leq k-1$, $g^{(k)}(\mu) \neq 0$. Then $\dfrac{g(Y_n) - g(\mu)}{\frac{1}{k!}g^{(k)}(\mu)\sigma_n^k} \xrightarrow{d} Z^k$ where $Z \sim N(0,1)$

Principles of Data Reduction

Definition
Let $\boldsymbol{X} = (X_1, X_2, ..., X_n)$ be a random sample from a population with unknown parameter θ. A statistic $T = T(\boldsymbol{X})$ is a **sufficient statistic** for θ if the conditional distribution of the sample $\boldsymbol{X}$ given $T = t$ does not depend on θ, i.e. $P(\boldsymbol{X} = (x_1, x_2, ..., x_n)|T = t)$ does not depend on θ

Remark
Sufficient if probability of sample vector given the statistic does not depend on the parameter

Theorem
Let $f(\boldsymbol{x}|\theta)$ denote the joint pdf or pmf of a sample $\boldsymbol{X}$ and $q(t|\theta)$ is the pdf or pmf of a statistic $T(\boldsymbol{X})$. Then $T(\boldsymbol{X})$ is a sufficient statistic for θ if for every $\boldsymbol{x}$ in the sample space, the ratio $\dfrac{f(\boldsymbol{x}|\theta)}{q(T(\boldsymbol{x})|\theta)}$ does not depend on θ.

Remark
Sufficient if joint pmf/pdf of sample vector divided by pmf/pdf of statistic does not depend on parameter.

Theorem (Factorization Theorem)
Let $f(\boldsymbol{x}|\theta)$ denote the joint pdf or pmf of a sample $\boldsymbol{X}$. A statistic $T(\boldsymbol{X})$ is a sufficient statistic for θ if and only if there exist functions $g(t|\theta)$ and $h(\boldsymbol{X})$ such that for all sample point $\boldsymbol{x}$ and all parameter points θ, $f(\boldsymbol{x}|\theta) = g(T(\boldsymbol{x})|\theta)h(\boldsymbol{x})$

Remark
Sufficient iff the joint pdf of the sample vector can be factorized into a function of the statistic (which depends on the parameter) and a function independent of the parameter. Not the function of the statistic need not be the pdf/pmf of the statistic

Note
The above theorem helps us construct sufficient statistics instead of guessing at them.

Note
It is always true that the entire sample is a sufficient statistics since $T(x) = x$ and $h(x) = 1$ satisfies the above theorem. But this does not help with data reduction.

Note
For samples from a normal distribution with parameters μ and σ^2, $T(\boldsymbol{X}) = (\overline{X}, S^2)$ is a sufficient statistic for (μ, σ^2). Note for other distributions, the sample mean and variance may not be sufficient.

Note
If T is sufficient for θ, then any one-one function of T is also sufficient.

Definition
Let $\{f(t|\theta), \theta \in \Theta\}$ (θ may be a vector) be a family of pdfs or pmfs for a statistic $T = T(\boldsymbol{X})$ (here T may be multidimensional). We say that this family is **complete** if given any real-valued function g with $E_\theta g(T) = 0$ for all $\theta \in \Theta$ then
$P_\theta(g(T) = 0) = 1$ for all $\theta \in \Theta$.

Note
If a statistic $T = T(X)$ is sufficient for the family of pdfs or pmfs $\{f(x|\theta)|\theta \in \Theta\}$ then T is sufficient for any subclass of $\{f(x|\theta)|\theta \in \Theta\}$.
This does not hold for completeness, if even one member is removed from the family, it destroys completeness.

Definition
We say that $\{f(x|\theta)|\theta \in \Theta\}$ is a **one-parameter exponential family** if $f(x|\theta)$ can be expressed as $f(x|\theta) = c(\theta)h(x)e^{w(\theta)t(x)}$ where $h(x) \geq 0$ and $t(x)$ are real valued functions of the observation x (cannot depend on θ), $c(\theta) \geq 0$ and $w(\theta)$ are real valued functions of the unknown parameter θ (cannot depend on x).

Definition
The form in the above definition is not unique.

Definition
We say that $\{f(x|\boldsymbol{\theta})|\boldsymbol{\theta} \in \Theta\}$ is a ***k*-parameter exponential family** if $f(x|\boldsymbol{\theta})$ can be expressed as $f(x|\boldsymbol{\theta}) = c(\boldsymbol{\theta})h(x)e^{\sum_{i=1}^{k} w_i(\theta)t_i(x)}$ where $h(x) \geq 0$ and $t_i(x), i = 1, 2, ..., k$ are real-valued functions of the observation x (cannot depend on $\boldsymbol{\theta} = (\theta_1, ..., \theta_k)$, $c(\boldsymbol{\theta}) \geq 0$ and $w_i(\boldsymbol{\theta}), i = 1, 2, ..., k$ are real-valued functions of the unknown k-dimensional parameter $\boldsymbol{\theta}$ (cannot depend on x)

Definition
We say that $\{f(x|\boldsymbol{\theta})|\boldsymbol{\theta} \in \Theta\}$ is a **curved exponential family** if $f(x|\boldsymbol{\theta})$ can be expressed in the form $f(x|\boldsymbol{\theta}) = c(\boldsymbol{\theta})h(x)e^{\sum_{i=1}^{k} w_i(\theta)t_i(x)}$ for which the dimension of the vector $\boldsymbol{\theta}$ is equal to $d < k$

Theorem
Let $X_1, X_2, ..., X_n$ be iid observations from a pdf or pmf $f(x|\boldsymbol{\theta})$ that belongs to an exponential family given by $f(x|\boldsymbol{\theta}) = c(\boldsymbol{\theta})h(x)e^{\sum_{i=1}^{k} w_i(\boldsymbol{\theta})t_i(x)}$ where $\boldsymbol{\theta} = (\theta_1, \theta_2, ..., \theta_d)$ where $d \leq k$. Then $T(\boldsymbol{X}) = \left(\sum_{j=1}^{n} t_1(X_j), ..., \sum_{j=1}^{n} t_k(X_j)\right)$ is a sufficient statistic for $\boldsymbol{\theta}$

Theorem
Let $X_1, X_2, ..., X_n$ be iid observations from a pdf or pmf $f(x|\boldsymbol{\theta})$ that belongs to a k-parameter exponential family given by $f(x|\boldsymbol{\theta}) = c(\boldsymbol{\theta})h(x)e^{\sum_{i=1}^{k} w_i(\boldsymbol{\theta})t_i(x)}$ where $\boldsymbol{\theta} = (\theta_1, \theta_2, ..., \theta_k)$. Then the statistic $T(\boldsymbol{X}) = \left(\sum_{j=1}^{n} t_1(X_j), ..., \sum_{j=1}^{n} t_k(X_j)\right)$ is complete for $\boldsymbol{\theta}$

Note
In the above theorems, curved exponential families are allowed in the sufficient statistic theorem, but only fully exponential families are allowed in the complete statistic theorem.
